Service outage response

When the service goes down, first check the health endpoint to confirm the outage.

Then look at the most recent deployment and the error rate in the logs.

If a recent release caused the failure, roll back to the previous version.

Post a status update every 30 minutes until the service is healthy again.

Leaked credential response

If a credential or API key is leaked, rotate it immediately and revoke the old one.

Search the audit log for any use of the leaked key and record what was accessed.

Remove the secret from the repository history and from any shared documents.

Notify the owner of the affected systems and document the timeline of the incident.
